

Lab 18 – VPC Security Groups

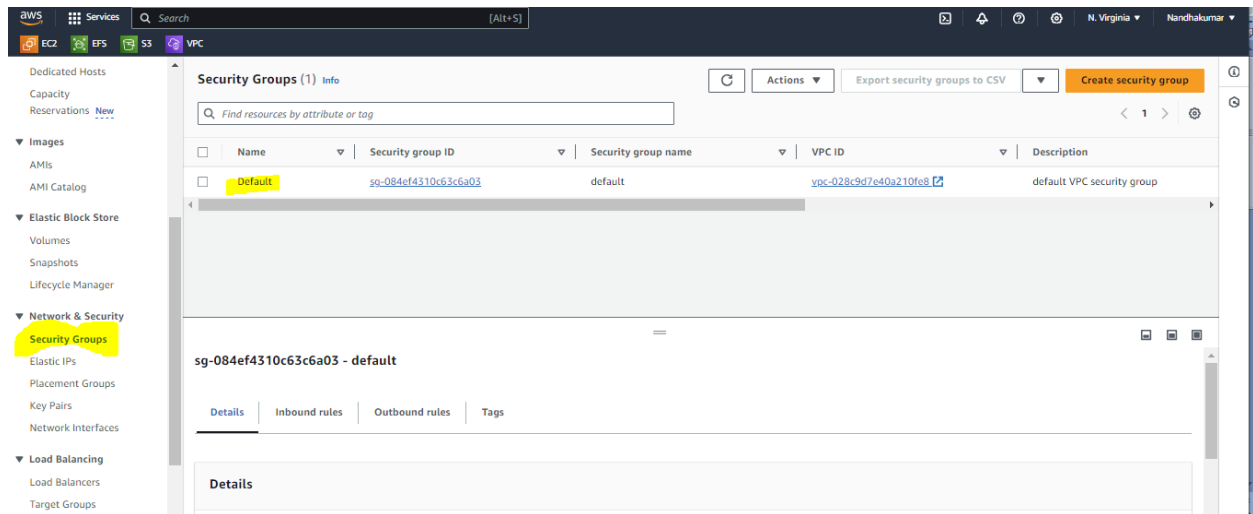

For Security group usually we will create while creating the instance like below image. But this time we creating in different way.

Before creating the security group create a VPC, One subnet(Public), One internet gateway, One Routing table(Public)

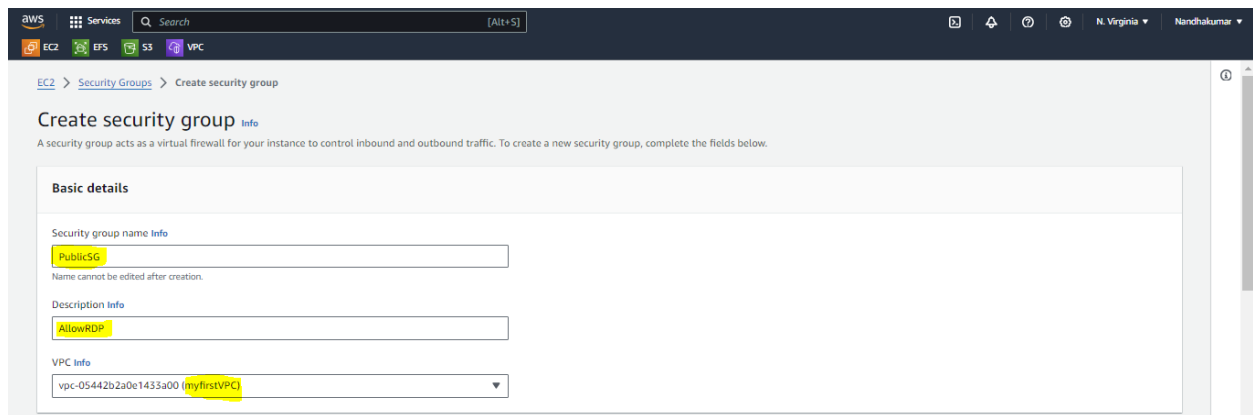

After that go to EC2->Network & security-> Security group

We can see default security group is already available. But we want to create a new security group

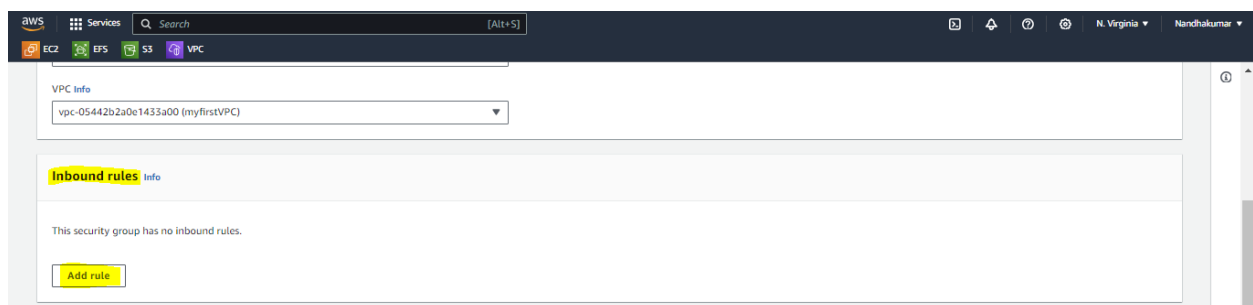

Security group is instance level security

Click Create security group

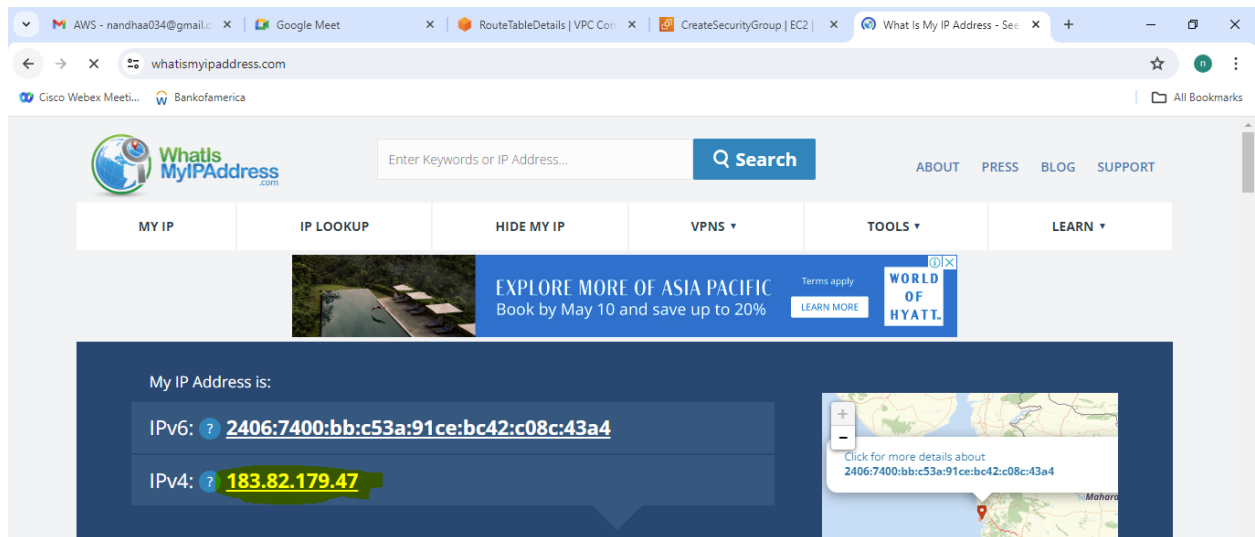

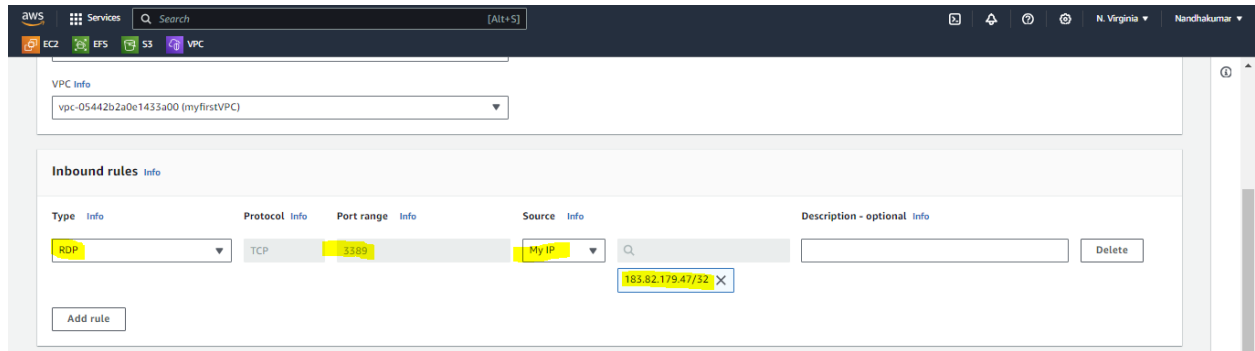

There is no default inbound rules in inbound. We want to create a rule

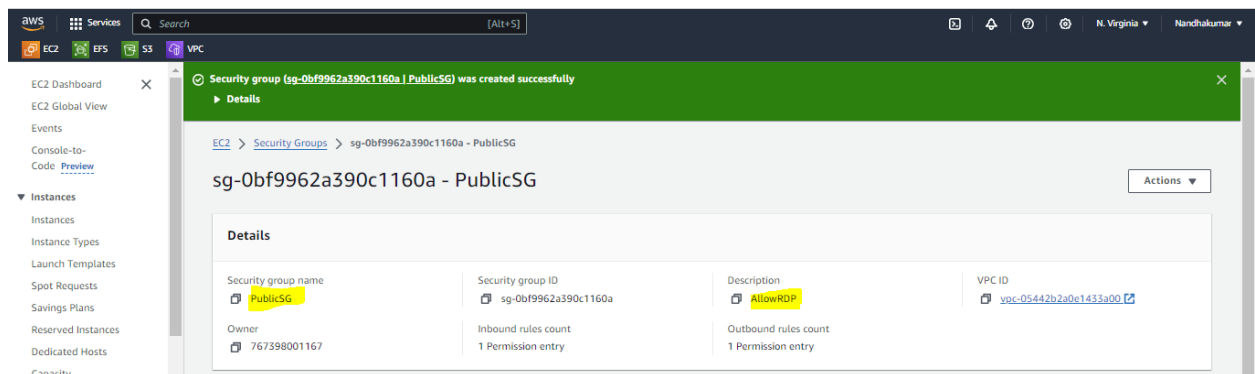

Once we select a RDP the port number automatically shows 3389 and source we set a My IP IP will automatically come.

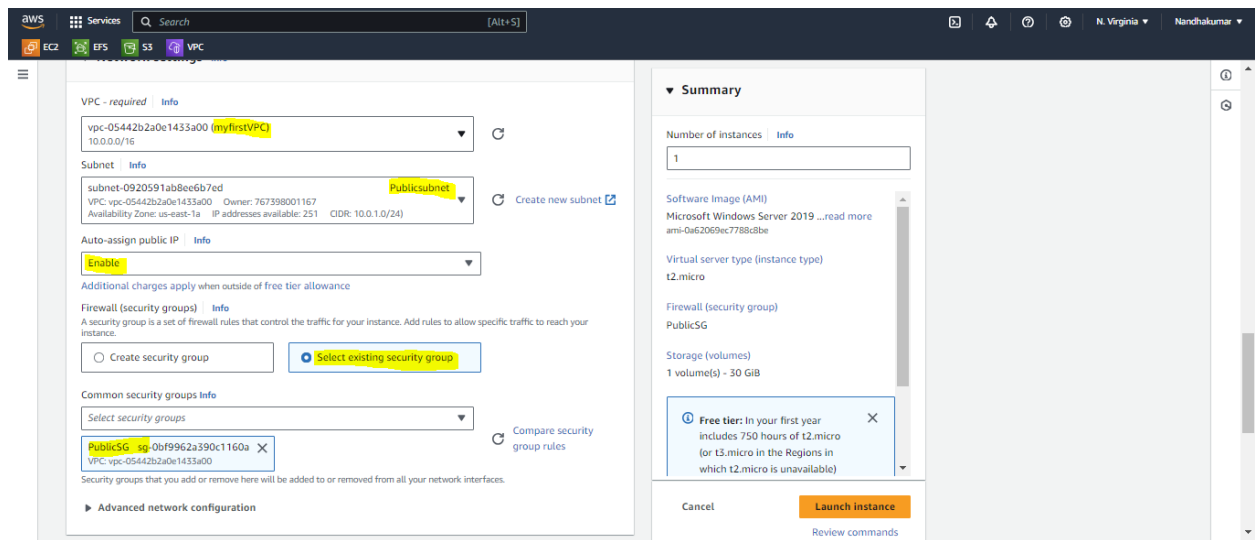

That IP is our own machine IP address. Search my IP address in google it will show the same IP address.

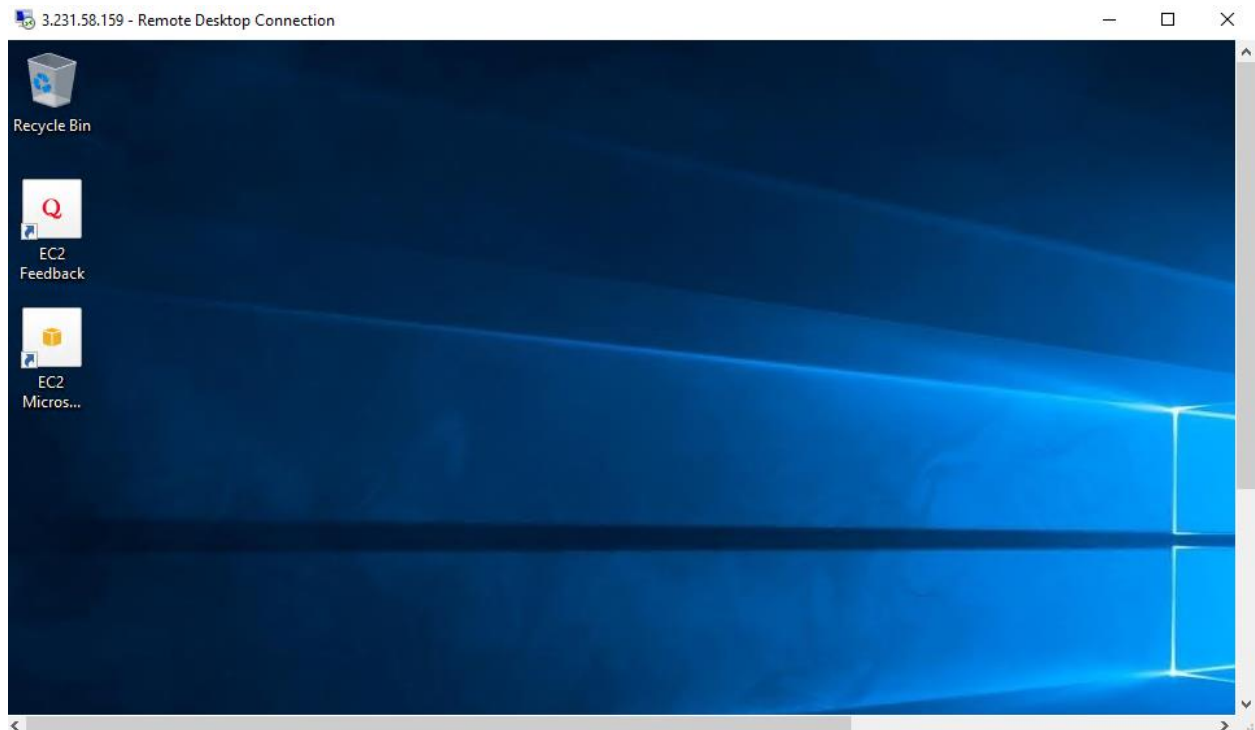

Security group has been created successfully.

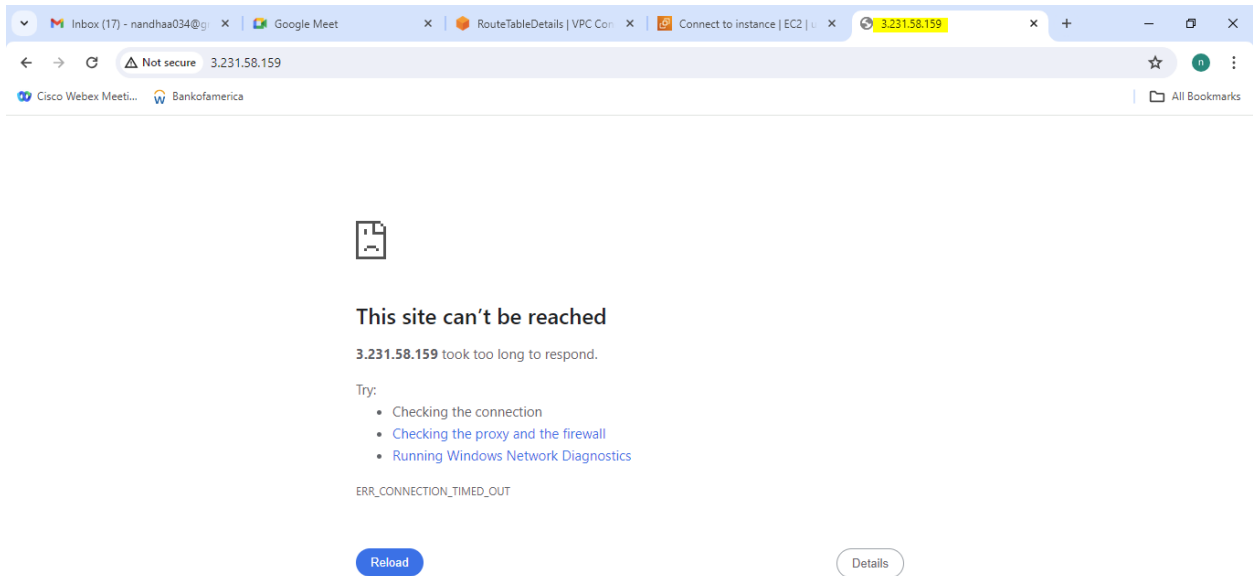

Now we can create a new instance. While creating instance select publicSG like below and launch instance

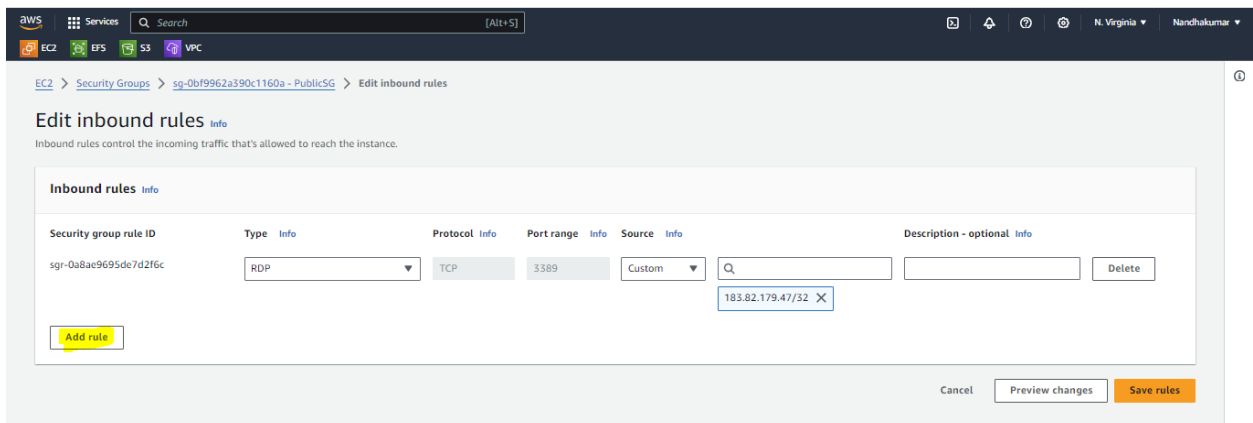

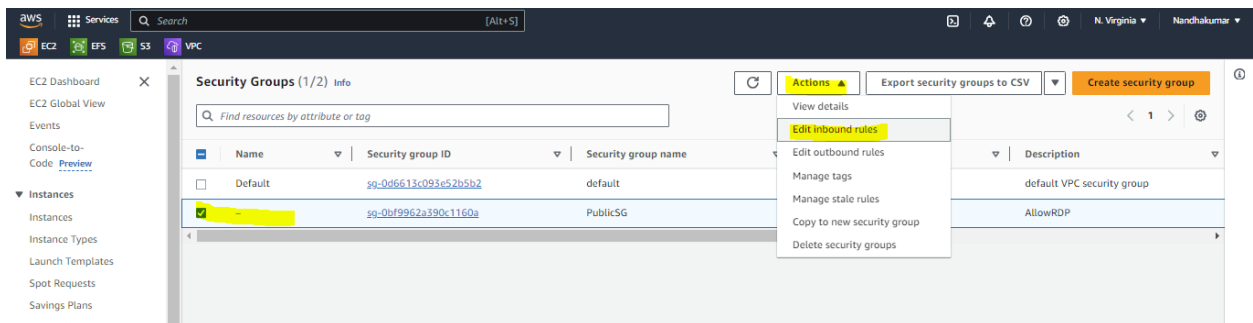

Now we can able to take a RDP successfully.

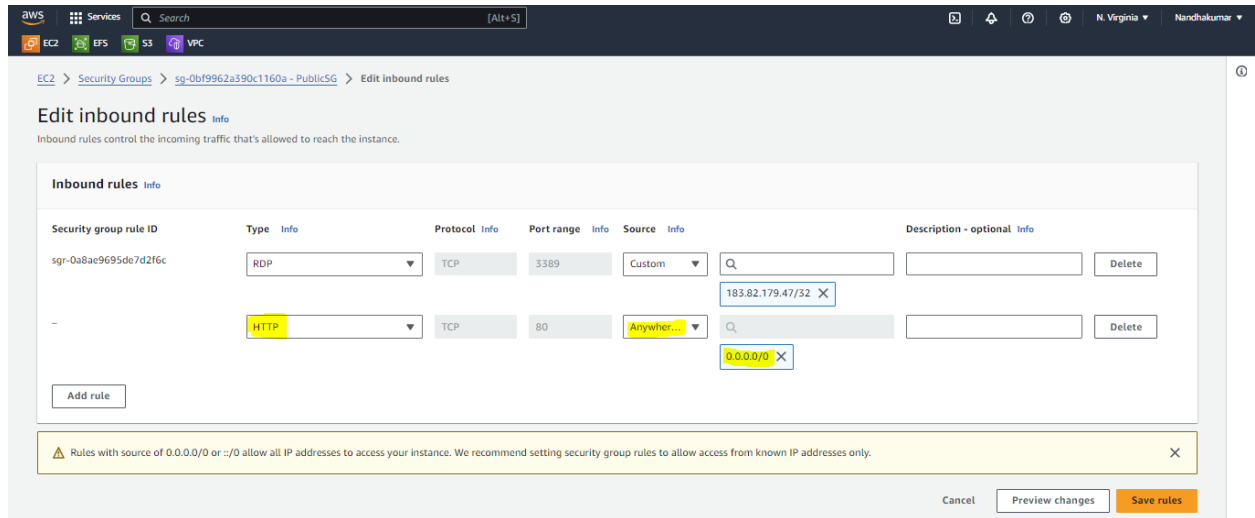

But we tried the same IP in browser it will won't work. Because we didn't allow http we allowed only RDP

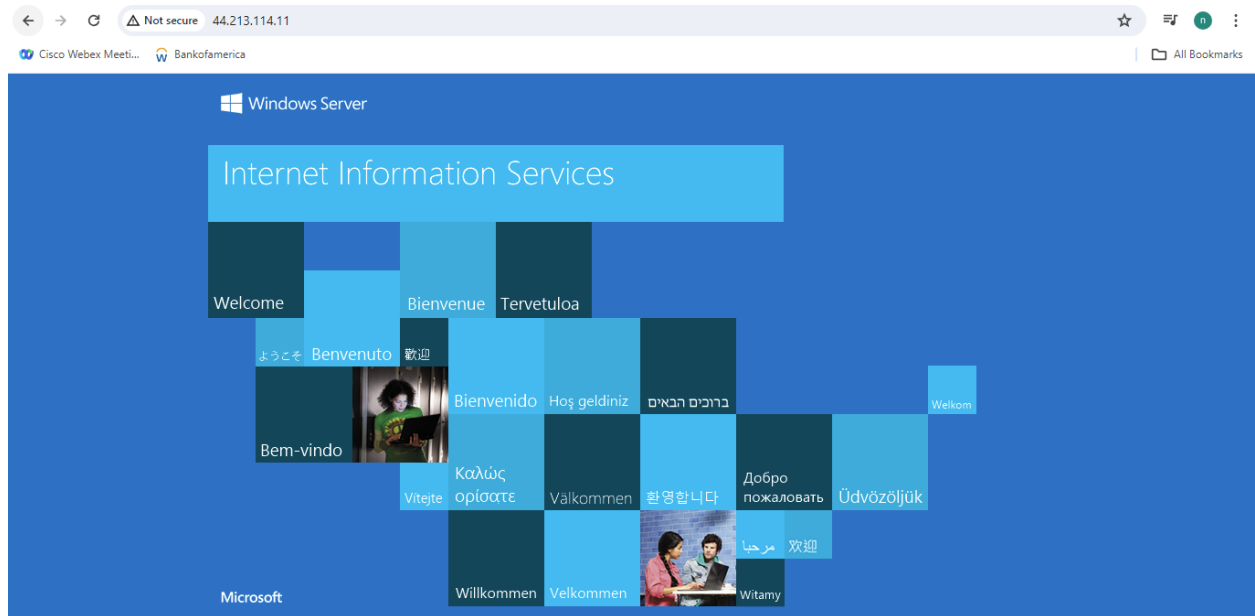

Now we going to allow the HTTP in inbound rules like below

Select HTTP and set the source. Click save rules.

Now we can access the same IP in browser we can able to connect successfully.

Inbound- all traffic coming towards VPC

Outbound- All traffic going from VPC
